

GitHub Deployment, Hosting, and PageSpeed Performance Report

Date: 2026-05-17 Site: <https://drranjithneuro.com/> Repository: <https://github.com/sivamohanbabu/Dr-Site> Hosting: GitHub Pages with custom domain

Executive Summary

The PageSpeed issue is not caused by a failed GitHub deployment. The latest GitHub Pages deployment completed successfully and is serving the latest `main` branch commit.

The remaining mobile PageSpeed issue is caused by live-site performance and hosting constraints:

- ? Mobile PageSpeed score from the latest screenshot: Performance 63, Accessibility 89, Best Practices 100, SEO 92.
- ? GitHub Pages deployment is successful for commit `aa1794044d21616d5881a932f008b3b095f7b854`.
- ? DNS points to GitHub Pages IPs.
- ? The repo contains an `.htaccess` file, but GitHub Pages does not run Apache `.htaccess` rules, so the intended cache, compression, redirect, and security header configuration cannot be relied on in this hosting environment.
- ? The homepage still has a large render path: Google Fonts, Bootstrap CSS, custom CSS, Font Awesome, many homepage sections, and many image cards.
- ? A public fetch path showed a bot-verification interstitial for the root domain during review. If Google PageSpeed receives that page instead of the real homepage, performance scoring can be distorted.

Deployment Chain

Source branch:

- ? Branch: `main`
- ? Local HEAD: `aa1794044d21616d5881a932f008b3b095f7b854`
- ? Remote origin/main: `aa1794044d21616d5881a932f008b3b095f7b854`
- ? Working tree at review time: `clean`

GitHub Actions / Pages deployment:

- ? Workflow: `pages build and deployment`
- ? Run: `25985728950`
- ? Run URL: <https://github.com/sivamohanbabu/Dr-Site/actions/runs/25985728950>
- ? Status: `completed`
- ? Conclusion: `success`
- ? Created: `2026-05-17T08:21:26Z`
- ? Updated: `2026-05-17T08:22:04Z`

Deployment record:

- ? Deployment ID: `4716881317`
- ? Environment: `github-pages`
- ? Ref: `main`
- ? SHA: `aa1794044d21616d5881a932f008b3b095f7b854`
- ? Status: `success`
- ? Environment URL reported by GitHub: <http://drranjithneuro.com/>

? Success time: 2026-05-17T08:22:04Z

Conclusion: GitHub has deployed the current main branch successfully. The PageSpeed problem is downstream of deployment success.

Hosting and DNS Findings

The domain is configured as an apex custom domain through GitHub Pages.

Observed DNS records:

? 185.199.108.153

? 185.199.109.153

? 185.199.110.153

? 185.199.111.153

These are GitHub Pages IPs.

GitHub Pages is a static hosting service. It does not behave like Apache hosting, so Apache-specific .htaccess directives in this repo should not be treated as active production configuration.

Important impact:

? ExpiresByType rules in .htaccess may not apply.

? Cache-Control rules in .htaccess may not apply.

? mod_deflate / mod_brotli rules in .htaccess may not apply.

? Rewrite rules in .htaccess may not apply.

? Security headers in .htaccess may not apply.

This matters because PageSpeed depends heavily on cache headers, compression, redirects, and asset delivery.

PageSpeed Status

Latest screenshot result:

Category	Score
Performance	63
Accessibility	89
Best Practices	100
SEO	92

PageSpeed API status:

? A live PageSpeed API request was attempted.

? Google returned 429 Too Many Requests, so a fresh full JSON Lighthouse report could not be downloaded during this review.

? The score above is therefore taken from the provided PageSpeed screenshot.

Google PageSpeed scores are Lighthouse-based lab scores plus field data when available. The screenshot also shows “No Data” for real-user data, so the visible score is primarily a lab diagnosis for this URL.

Performance Work Already Present

The current homepage includes several optimization attempts:

? Hero image is preloaded:

- ? images/sliders/4.webp
- ? Below-fold images use loading="lazy".
- ? Homepage uses optimized replacements:
 - ? images/aboutttt-optimized.jpg
 - ? images/wjy-choose-optimized.jpg
- ? Google Fonts are loaded with display=swap.
- ? Some CSS is preloaded with async stylesheet activation.
- ? JavaScript is deferred.
- ? Bootstrap JS is delayed until after page load / idle.
- ? Local homepage asset references were checked and all exist.

Image savings from current optimized replacements:

Asset	Before	After	Saved
aboutttt.png to aboutttt-optimized.jpg	1381 KB	84 KB	1297 KB
wjy-choose.png to wjy-choose-optimized.jpg	1202 KB	98 KB	1104 KB

Remaining Performance Risks

High-priority risks:

1. .htaccess is not active on GitHub Pages

The repo contains performance headers, compression rules, and redirects in .htaccess, but GitHub Pages will not apply Apache config. This can keep PageSpeed warnings unresolved even after code changes.

1. Hosting cannot fully control cache/compression headers

GitHub Pages is simple static hosting. For strict PageSpeed tuning, a host/CDN that supports _headers, edge rules, Brotli, and explicit immutable cache headers is better.

1. Possible bot-verification / interstitial behavior

A public web fetch returned a "Verifying that you are not a robot..." page during review. If PageSpeed receives that response path, Lighthouse may audit the interstitial instead of the homepage.

1. Render path remains heavy on mobile

The homepage still loads several CSS dependencies and a large DOM:

- Bootstrap CSS: about 293 KB - custom.css: about 120 KB - Font Awesome CSS: about 121 KB - Google Fonts - Large HTML document: about 66-68 KB - 15 service cards on the homepage

1. External font request can affect first paint

Google Fonts can still delay text rendering or increase network work on mobile. Self-hosting only the exact used font weights would be more predictable.

Why the Score Can Stay at 63

The score can remain low even when deployment succeeds because GitHub Pages deployment only confirms files were published. It does not confirm:

- ? PageSpeed saw the newest uncached HTML.
- ? PageSpeed saw the real homepage instead of a verification page.

- ? Intended .htaccess performance headers were applied.
- ? Mobile Lighthouse main-thread and render-blocking time became low enough for a green score.

Recommended Fix Plan

Priority 1: Hosting / header fix

- ? Move the site to a static host/CDN that supports custom headers, such as Cloudflare Pages, Netlify, or Vercel.
- ? Add equivalent `_headers` configuration for:
 - ? Long cache for images, fonts, CSS, and JS.
 - ? Short/no-cache for HTML.
 - ? Brotli/gzip compression where supported.
 - ? Security headers.

Priority 2: Remove the bot-verification path

- ? Check domain/DNS/security provider settings.
- ? Ensure Googlebot, Lighthouse, PageSpeed Insights, and normal anonymous users receive the real homepage HTML without an interstitial.

Priority 3: Reduce render-blocking CSS

- ? Split critical homepage CSS from full site CSS.
- ? Load only above-the-fold CSS synchronously.
- ? Delay Font Awesome or replace above-the-fold icons with inline SVG or lightweight assets.
- ? Remove unused Bootstrap rules with a build step if staying on Bootstrap.

Priority 4: Reduce homepage work

- ? Consider showing fewer service cards on the homepage and linking to the full services page.
- ? Keep homepage first viewport focused on hero, intro, and primary services.
- ? Move non-essential animated effects out of the mobile experience.

Priority 5: Font optimization

- ? Self-host only the used Sora and Marcellus weights.
- ? Preload WOFF2 font files.
- ? Use fallback font metrics to reduce layout shifts.

Verification Checklist After Fixes

Run these checks after the next deployment:

1. Confirm GitHub/hosting deployment status is successful.
2. Fetch the live HTML and confirm it contains:

- aboutttt-optimized.jpg - wjy-choose-optimized.jpg - no homepage animate.css - no homepage mousecursor.css

1. Confirm the live response is the homepage, not a bot-verification page.
2. Confirm image/CSS/JS responses have correct `Cache-Control`.
3. Confirm HTML response is not cached too aggressively.
4. Rerun PageSpeed mobile 2-3 times and compare metrics, not only the score:

- LCP - FCP - TBT - CLS - Speed Index

Final Assessment

Deployment status: Passed GitHub Pages publishing: Passed DNS to GitHub Pages: Passed Best Practices: Passed at 100 SEO: Good at 92 Accessibility: Needs minor improvement at 89 Mobile Performance: Still unresolved at 63

The blocker is not GitHub deployment failure. The blocker is production delivery and remaining mobile render-path cost, especially because .htaccess optimizations are not a dependable production mechanism on GitHub Pages.
