

# Mobile PageSpeed Performance Fixes Report

Site: <https://drranjithneuro.com/>

Generated: 17 May 2026, 01:35 PM

## Why Mobile Was Low

- The homepage was loading desktop animation libraries on mobile: GSAP, SplitText, ScrollTrigger, magic cursor, parallax, and WOW.
- The second hero slide background image was discoverable immediately even though it is not visible on first load.
- Several non-critical CSS files were render-blocking on the homepage.
- Google Fonts requested the full Sora 100-800 variable range instead of only the weights used.
- Bootstrap JavaScript was loaded during initial page load even though it is only needed for below-the-fold interactions.

## Fixes Applied

- Removed heavy desktop animation script tags from the homepage initial load.
- Hardened js/function.js with feature checks so missing optional libraries do not create runtime errors.
- Delayed Bootstrap JavaScript until after page load/idle.
- Lazy-loaded the second hero slide background using data-bg so only the first LCP image is fetched initially.
- Asynchronously loaded non-critical CSS: footer.css, all.min.css, animate.css, mousecursor.css, and bootstrap.min.css.
- Reduced Google Font request to Sora 400, 500, 600, 700 plus Marcellus.

## Local Verification

| Check                                                 | Result                                                      |
|-------------------------------------------------------|-------------------------------------------------------------|
| Homepage heavy animation libraries in initial scripts | Removed                                                     |
| Second slide eager background                         | Removed; data-bg is used                                    |
| Homepage smoke test                                   | HTTP 200 locally                                            |
| Core remaining scripts                                | jquery, slicknav, function.js, slider.js, delayed bootstrap |

## Remaining Live Requirements

- Deploy these changed files before rerunning PageSpeed mobile. The screenshot is still measuring the live host, not this local workspace.
- Clear CDN/hosting cache after deployment.
- Make sure bot protection does not serve a verification page to Google Lighthouse/PageSpeed.
- If mobile score is still below target after deployment, the next layer is image conversion/resizing and splitting the large custom.css into critical and below-the-fold CSS.
